

Project 2 Report - Opponent Avoidance Problem

Chanran Kim (shining04@csu.fullerton.edu)

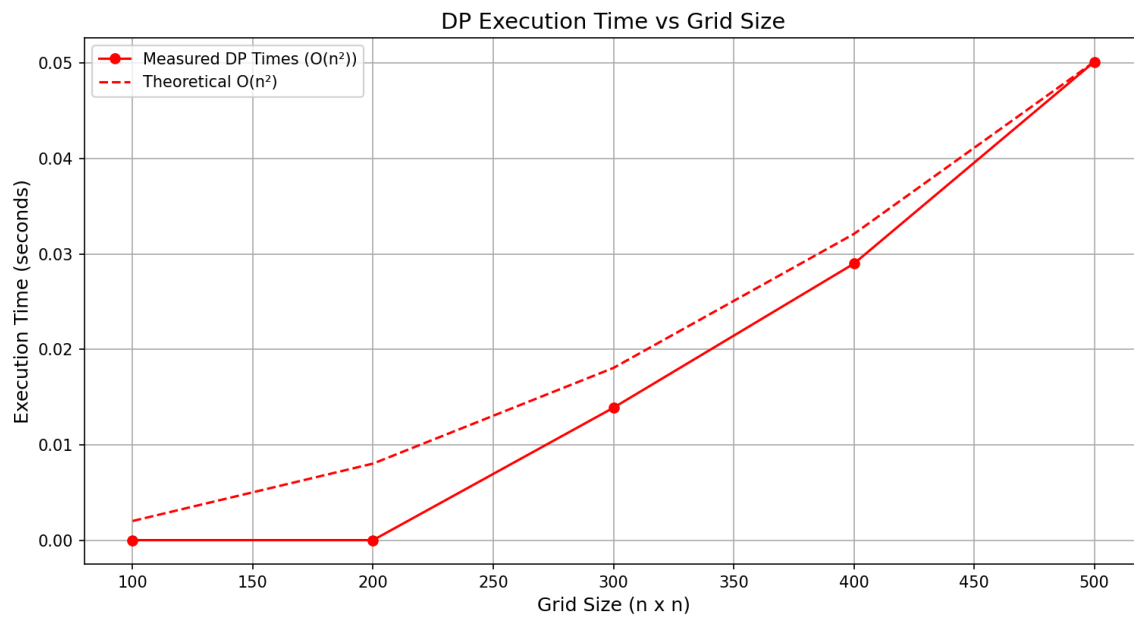

Brian Alvarez (briandalvarez@csu.fullerton.edu)

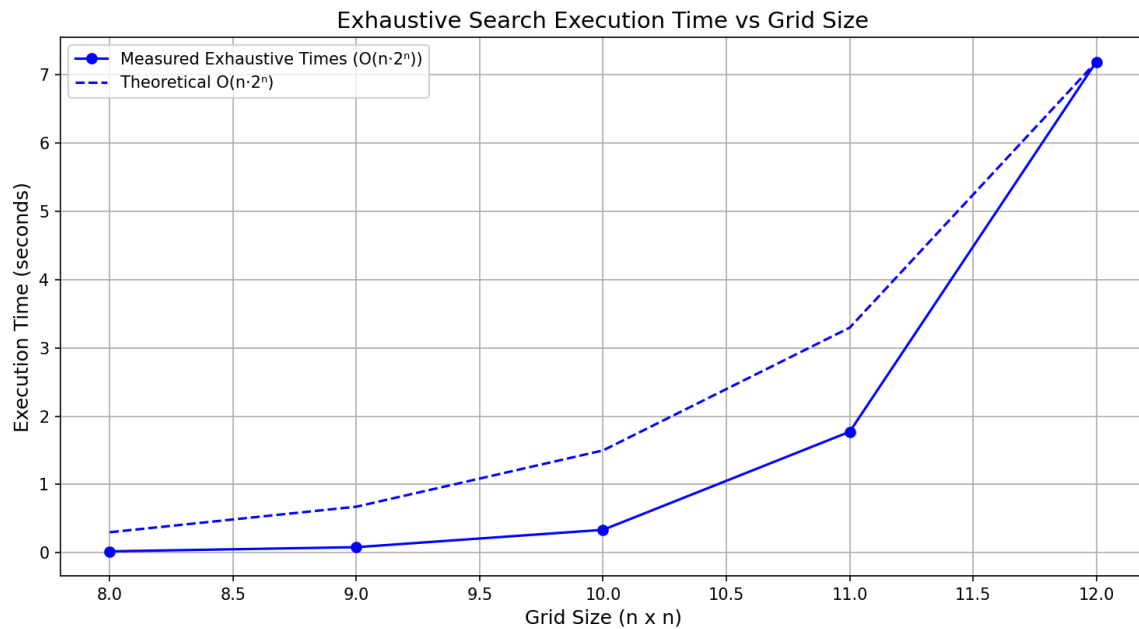

Christopher Contreras (CContreras71@csu.fullerton.edu)

Vinh Nguyen(vinhgod123@csu.fullerton.edu)

A. Scatter plots for each of two algorithms.

```
DP Sizes: [100, 200, 300, 400, 500]
DP Times: [0.0, 0.0, 0.013883, 0.028984, 0.050157]
Exhaustive Sizes: [8, 9, 10, 11, 12]
Exhaustive Times: [0.019655, 0.080951, 0.334803, 1.771319, 7.190151]
```

B. Answers to the questions (Each answer should be at least one complete sentence.)

I. Is there a noticeable difference in the performance of the two algorithms?

There is a noticeable difference in performance as the Dynamic programming algorithm performs a lot better when the grid size increases. On the other hand, Exhaustive search peaks at 7 seconds when it reaches a grid size of 12.

II. According to your experimental observation, which of the implementations is faster, and by how much?

The implementation that is faster and even more efficient would be the Dynamic programming. Dynamic programming is faster by a huge amount. As you can see in the output and the scatter plots, even at a 500 grid size it is still faster than Exhaustive search at a grid size of 12 by a whole 7 seconds.

III. Are your empirical analyses consistent with the predicted big-O efficiency class for each algorithm? Justify your answer.

For the exhaustive search, our analysis is consistent with the predicted big-O efficiency because, as you can see, the ES has an exponential growth which demonstrates a high complexity time faulting in a big-O notation of (2^n) . It is too slow as the grid number moves up. As for dynamic programming, it demonstrates a polynomial growth which resulted in slower time as the grid number moves up. Therefore, the notation of dynamic programming is (n^2) .

IV. Is this evidence consistent or inconsistent with hypothesis 1? Justify your answer.

With the evidence that we've collected, we can support that the hypothesis is consistent. The reason for this is Exhaustive search is a $O(2^n)$ notation and therefore implements an exponential running time. Which means that it would take its time to search for all possible solutions, resulting in a longer running time. It double-checks every solution and eventually results in the most optimal solution.

V. Is this evidence consistent or inconsistent with hypothesis 2? Justify your answer.

With all the evidence that we've collected, we believed that the hypothesis would be consistent with our evidence. Since, Exhaustive search take extremely long for any algorithm to use as it is a $O(2^n)$. Therefore, it would hinder any program that tried to use this algorithm for practical use.
